

Causality and Causal Misperception in Dynamic Games

Sungmin Park

The Ohio State University

November 12, 2024

What I do

Question How should we capture players' **misperceptions** about **causality** in extensive-form games?

Answer Let each player best respond to a **belief** about Nature and others' actions **consistent with observed outcomes**

“Observation-consistent equilibrium (OE)”

What I do

Question How should we capture players' **misperceptions** about **causality** in extensive-form games?

Answer Let each player best respond to a **belief** about Nature and others' actions **consistent with observed outcomes**

“Observation-consistent equilibrium (OE)”

What I do

Question How should we capture players' **misperceptions** about **causality** in extensive-form games?

Answer Let each player best respond to a **belief** about Nature and others' actions **consistent with observed outcomes**

“Observation-consistent equilibrium (OE)”

Motivation

People have varying perceptions of causality

Causality: How actions affect outcomes

Simplest example

- Smoker chooses to **smoke** ($s = 1$) or **not** ($s = 0$).
 - If he smokes, Nature gives him cancer with prob $\pi_1 = 2/3$.
 - If not, Nature gives him cancer with prob $\pi_0 = 1/3$.
- He gets $r < \frac{1}{3}$ if he smokes and loses 1 if he gets cancer.
- Smoker's **strategy** is the prob $\sigma \in [0, 1]$ of smoking.
- Smoker's **belief** is $\beta = (\beta_0, \beta_1)$ where β_s is the subjective probability of getting cancer given s .

Smoker's Problem

⇒ Under **rational expectations**, one shouldn't smoke because the **causal effect** of smoking on cancer ($\frac{2}{3} - \frac{1}{3} = \frac{1}{3}$) is larger than the **reward** r

Observational consistency

Definition

Given strategy $\sigma \in [0, 1]$, a belief $\beta \in [0, 1]^2$ is **observation-consistent** if

$$\underbrace{\sigma\beta_1 + (1 - \sigma)\beta_0}_{\text{perceived marginal prob of cancer}} = \underbrace{\sigma \cdot \frac{2}{3} + (1 - \sigma) \cdot \frac{1}{3}}_{\text{actual marginal prob of cancer}}$$

Interpretation

- Smoker sees a population of smokers choosing σ overall and sees the overall **rate of cancer** patients, but do not know the conditional probabilities
- What the smoker **thinks** Nature does (β_0, β_1) and what Nature **really** does $(\frac{1}{3}, \frac{2}{3})$ are **observationally equivalent**

Illustration of an observational consistency

Suppose I smoke half of the time ($\sigma = 0.5$).

What I **think** Nature does

What Nature **really** does

Remark: There are many observation-consistent beliefs.

Principle of Maximum Entropy

Notation

- $\mathbf{p}(\sigma, \beta)$: vector of probabilities over the 4 terminal nodes.
- $G(\cdot)$: Shannon entropy function.

Definition

Given strategy $\sigma \in (0, 1)$, an observation-consistent belief $\beta^* \in [0, 1]^2$ **maximizes the entropy** if

$$\beta^* \in \operatorname{argmax}_{\beta \text{ is obs-cons}} G(\mathbf{p}(\sigma, \beta)).$$

Interpretation

- Among many worldviews consistent with observation, choose the one that **assumes the least information**

Illustration of maximum entropy

A point prediction on belief

Maximum entropy \Rightarrow correlation neglect

Claim

For every $\sigma \in (0, 1)$, the maximum-entropy belief β^* satisfies

$$\beta_0^* = \beta_1^* = (1 - \sigma) \cdot \frac{1}{3} + \sigma \cdot \frac{2}{3}.$$

Meaning The smoker doesn't think smoking **causes** cancer

Intuition The smoker observes **no evidence** of dependence between smoking and cancer, so he **believes in none**.

General result (Shore and Johnson, 1980; Csiszar, 1991)

Maximum entropy \Leftrightarrow **correlation neglect**, whenever agents observe only the marginal prob. distribution between two variables

Equilibrium

Definition

A strategy-belief pair (σ, β) is an **observation-consistent equilibrium (OE)** if

- ① Given the belief β , the strategy σ is a **best response (subjectively)**, and
- ② Given the strategy σ , the belief β is an **observation-consistent**.

Result on OE

Every strategy is rationalizable by some observation-consistent belief

Claim

Every strategy σ has a belief β such that (σ, β) is an OE.

Note: Specifically, the OCE equilibria are

- ① $\sigma = 0$, $\beta_0 = \frac{1}{3}$, and $\beta_1 - \beta_0 \geq r$,
- ② $\sigma = 1$, $\beta_1 = \frac{2}{3}$, and $\beta_1 - \beta_0 \leq r$, and
- ③ $\sigma \in (0, 1)$, $\beta_0 = \sigma \cdot (\frac{2}{3} - r) + (1 - \sigma) \cdot \frac{1}{3}$, and $\beta_1 = \sigma \cdot \frac{2}{3} + (1 - \sigma)(\frac{1}{3} + r)$.

Idea Because there are many observation-consistent beliefs, there are many OEs.

Refinement of OE

Definition

An OE (σ, β) is a **maximum-entropy observation-consistent equilibrium (MOE)** if there exists a sequence of strategy-belief pairs

$$\{(\sigma^k, \beta^k)\}_{k=1}^{\infty} \longrightarrow (\sigma, \beta)$$

such that each σ^k is a totally mixed strategy and each β^k maximizes the entropy.

Result on MOE

A sharper prediction

Claim

A strategy-belief pair (σ, β) is an MOE if and only if

$$\sigma = 1 \quad \text{and} \quad \beta_0 = \beta_1 = \frac{2}{3}.$$

Meaning

- Smoker **keeps smoking** while thinking that smoking **doesn't cause cancer**

Intuition

- MaxEnt OCE implies **correlation neglect**, so no other strategy is a best response.

Generalizing the observational structure

Motivation

- Correlation neglect sounds too naïve. Can we make agents more sophisticated? Yes! Give them **better observation**

Definition

Given an **observational structure** C (a matrix) and strategy σ , a belief β is **observation-consistent** if

$$C\mathbf{p}(\sigma, \beta) = C\mathbf{p}(\sigma, \pi).$$

Examples of C :

$$\begin{bmatrix} 1 & 1 & 1 & 1 \end{bmatrix}$$

$$\begin{bmatrix} 1 & \cdot & 1 & \cdot \\ \cdot & 1 & \cdot & 1 \end{bmatrix}$$

$$\begin{bmatrix} 1 & \cdot & \cdot & \cdot \\ \cdot & 1 & \cdot & \cdot \\ \cdot & \cdot & 1 & \cdot \\ \cdot & \cdot & \cdot & 1 \end{bmatrix}$$

$$\begin{bmatrix} 1 & 2 & 3 & 4 \end{bmatrix}$$

Generalizing the approach to extensive-form games

Finite extensive-form game with perfect recall + **observational constraint**

- N : set of players,
- H : set of histories (nodes), of which Ω is the set of terminal histories
- ι : mapping of non-terminal histories to players,
- π : probability distribution of Nature's moves,
- \mathcal{I} : collection of information sets,
- u : payoff function, and
- C : **observational structure**, a linear map $\Delta(\Omega) \rightarrow \mathbb{R}^\ell$

Theorem (Preview)

Every finite extensive-form game with perfect recall and observational constraint has an MOE.

Precise definition of equilibrium

Notation. (σ, β, μ) is a profile of strategies, beliefs, and posterior functions

Definition

A triple (σ, β, μ) is an **observation-consistent equilibrium (OE)** if for every player i ,

- 1 the strategy σ_i is (subjectively) sequentially rational given (β_i, μ_i) ,
- 2 the belief β_i is observation-consistent given the strategy profile σ :

$$C\mathbf{p}(\sigma_i, \beta_i) = C\mathbf{p}(\sigma_i, (\sigma_{-i}, \pi)), \text{ and}$$

- 3 the posterior function μ_i is Bayes-consistent given (σ_i, β_i) .

Precise definition of the refinement

Given a strategy profile σ , a player's observation-consistent belief β_i **maximizes the entropy** if

$$\beta_i \in \operatorname{argmax}_{\beta'_i \text{ is obs-cons}} G(\mathbf{p}(\sigma_i, \beta'_i)).$$

Definition

An OE (σ, β, μ) is a **maximum-entropy observation-consistent equilibrium (MOE)** if there exists a sequence

$$\{\sigma^k, \beta^k\}_{k=1}^{\infty} \longrightarrow (\sigma, \beta)$$

where each σ^k is a totally mixed strategy profile and each player's belief β_i^k maximizes the entropy.

Existence of MOE

Theorem

Every finite extensive-form game with perfect recall and observational constraint has an MOE.

Meaning

- There always exists a prediction where everyone **best responds** to what they **think** how others play, assuming the **least information** beyond observation.

Key proof step

- With **ϵ -constrained strategies**, mappings from a strategy profile σ to a maximum-entropy belief profile β_i and posterior function β_i are well-behaved.

Example: Ultimatum-like game with causal misperception

Manager-Worker game

- Manager (Player 1) decides a **fair** or **unfair** bonus to Worker (Player 2)
- Even if Manager chooses a fair bonus, Nature might change it to **unfair** or keep it **fair**
- If Worker receives fair bonus, he accepts. If not, he either **accepts** or **rejects**.
 - He gets a thrill for rejecting an unfair Manager
- Worker doesn't know how likely Manager treats him unfairly in the **interim** or **ex post**

$$C = \begin{bmatrix} 1 & \cdot & 1 & \cdot & \cdot \\ \cdot & 1 & \cdot & 1 & \cdot \\ \cdot & \cdot & \cdot & \cdot & 1 \end{bmatrix}$$

Unique MOE

Manager always tries to be fair

What Worker thinks they do

What they really do

Example: A centipede game

Figure: A four-node centipede game

Claim

Let the observational structure be $C = [0 \ 1 \ 2 \ 3 \ 4]$. There exists no MOE in which Alice Takes immediately.

Unique MOE of the centipede game

Each thinks the other mixes more than they really do

What Alice thinks they do

What Bob thinks they do

What they really do

How to interpret the observational structure C

Literal interpretation

- C represents the **actual observable outcomes** in a population of players

Metaphorical interpretation

- C represents how players **psychologically process** observable outcomes

Literature

Bridging behavioral theory and standard game theory

Behavioral theory

(Spiegler, 2020, 2021, etc.)

- Single-person decisions
- Directed Acyclic Graphs
- Maximum-entropy beliefs
- Subjective best responses

$$C = \begin{bmatrix} & \\ & \end{bmatrix}$$

My paper (MOE)

- Multiple players
- Observational structure (C)
- Maximum-entropy beliefs
- Subjective best responses

Standard game theory

(Kreps and Wilson, 1982, etc.)

- Multiple players
- Perfect observation
- Correct beliefs
- Objective best responses

Special case when players observe outcomes perfectly

Proposition

Suppose the observational structure C is the identity. Then

$$\begin{array}{ll} \text{OE} & \iff \text{Self-confirming equilibrium}^*, \text{ and} \\ \text{MOE} & \iff \text{Perfect Bayesian equilibrium.} \end{array}$$

* Version with sequential rationality.

\Rightarrow OE and MOE nest standard concepts as special cases

Frequently Asked Questions

How is MOE different from _____?

- Self-confirming equilibrium

Battigalli and Guaitoli (1988); Battigalli (1997); Fudenberg and Levine (1993)

- Analogy-based expectation equilibrium

Jehiel (2005); Jehiel and Koessler (2008); Jehiel (2022)

- (Sequential) Cursed equilibrium

Eyster and Rabin (2005); Cohen and Li (2022); Fong et al. (2023)

- Berk-Nash equilibrium

Esponda and Pouzo (2016)

MOE and Common Causal Misperceptions

- ① Correlation neglect
- ② Omitted-variable bias (selection neglect)
- ③ Simultaneity bias (reverse causality bias)

1. A two-stage game of correlated consequences

Players

$$N = \{1, 2, \dots, n\}$$

Stages

1. Players choose **actions** $x = (x_i)_{i \in N}$.
2. Nature chooses a **consequence** $y = (y_1, y_2)$
with conditional probability $\pi(y|x) > 0$ for all (x, y) .

Payoffs

$$u_i(x, y)$$

Obs. structure

Marginal probabilities of pairs (x, y_1) and (x, y_2)

Correlation neglect

Proposition

An OE (σ, β, μ) is a MOE if and only if for every player i ,

$$\begin{aligned}\beta_i(x_{-i}) &= \sigma_{-i}(x_{-i}) && \text{for all } x_{-i}, \text{ and} \\ \beta_i(y_1, y_2 | x) &= \pi(y_1 | x) \pi(y_2 | x) && \text{for all } x \text{ and } (y_1, y_2).\end{aligned}$$

Meaning In an MOE, players believe y_1 and y_2 remain (conditionally) **independent** regardless of their actions x .

Example Let x be whether an investment bank issues **mortgage-backed securities** or not. Let y be the **default outcomes** of two households.

Stylized example of correlation neglect

What I think how mortgage-backed securities (MBS) work

How they really work

Figure: Effects of MBS on household default probabilities

2. An omitted-variable game

Players

$$N = \{1, 2, \dots, n\}$$

Stages

1. Nature assigns a **state** t with probability $\pi(t)$.
2. Players see the state t and choose **actions** $x = (x_i)_{i \in N}$.
3. Nature chooses a **consequence** y with probability $\pi(y|t, x)$.

Payoffs

$$u_i(t, x, y)$$

Obs. structure

Marginal probabilities of pairs (t, x) and (x, y)

Omitted-variable bias (selection neglect)

Proposition

An OE (σ, β, μ) is an MOE if and only if every player's belief β_i satisfies,

$$\beta_i(t) = \pi(t),$$

$$\beta_i(x_{-i}|t) = \sigma_{-i}(x_{-i}|t), \text{ and}$$

$$\beta_i(y|t, x) = \sum_{t' \in \mathcal{T}} \pi(y|t', x) w(t', x) \quad \text{for all } (t, x, y).$$

Note: $w(\cdot)$ is a weight function such that $w(t', x) = \lim_{k \rightarrow \infty} \frac{\sigma^k(x|t')\pi(t')}{\sum_{t'' \in \mathcal{T}} \sigma^k(x|t'')\pi(t'')}$, for some sequence $\{\sigma^k\}_{k=1}^{\infty}$ of totally mixed strategy profiles converging to σ .

Meaning Players believe the **effect** of x on y is the **same** across states t

Stylized example of omitted-variable bias

Figure: Effects of college education on employment

3. Simultaneity game

Players $N = \{1, 2, \dots, n\}$

Stages (1) Nature assigns a **state** $t \in \{\text{Forward}, \text{Reverse}\}$ with probability $\pi(t)$.

If $t = F$, (2) players learn t and choose **actions** $x = (x_i)_{i \in N}$ and

(3) Nature chooses consequence y with prob $\pi(y|F, x)$.

If $t = R$, (2) Nature chooses consequence y with prob $\pi(y|R)$ and

(3) players learn (t, y) and choose **actions** $x = (x_i)_{i \in N}$.

Payoffs $u_i(t, x, y)$

Obs. structure Marginal probabilities of the pair (x, y)

Stylized example of simultaneity (reverse causality) bias

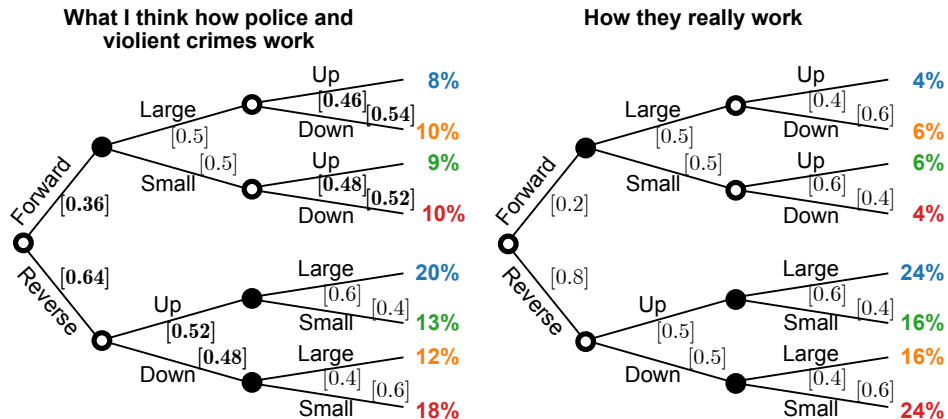

Figure: Effects of police size on violent crime rates

Wait... what do I even mean by causality?

Notation $p(\sigma_i, \beta_i)(E|h)$ is the subjective probability of **event** $E \subset \Omega$ given **history** h , **strategy** σ_i , and **belief** β_i .

Definition

Let (σ, β, μ) be an OE. An action a instead of b is a **subjective cause** of an event $E \subset \Omega$ given history h to player i if

$$p(\sigma_i, \beta_i)(E|h, a) > p(\sigma_i, \beta_i)(E|h, b).$$

An action a instead of b is an **objective cause** of an event $E \subset \Omega$ given history h to player i if

$$p(\sigma_i, (\sigma_{-i}, \pi))(E|h, a) > p(\sigma_i, (\sigma_{-i}, \pi))(E|h, b).$$

Extension: Infinite-horizon games

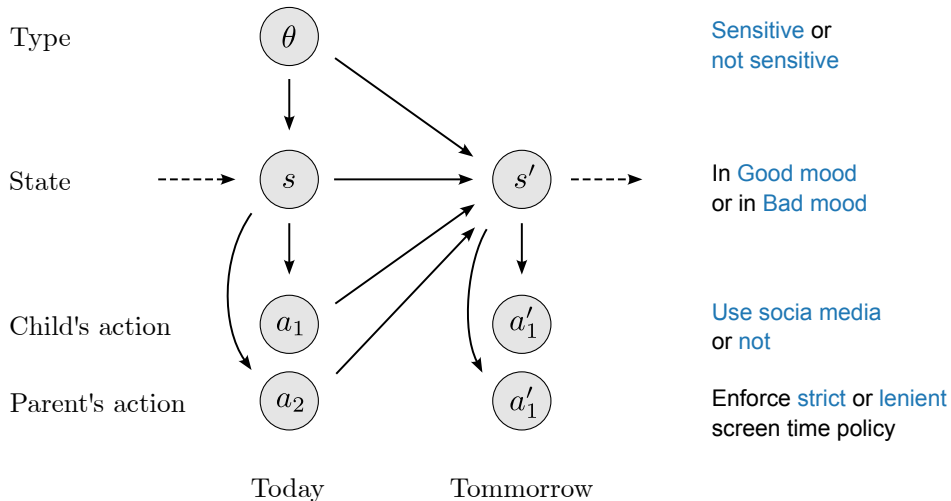

Figure: Stochastic game with permanent game types θ

Proposition

If players perfectly observe steady-state outcomes (θ, s, a, s') ,

MOE \iff Markov perfect equilibrium (MPE).

Illustration: Parent-Child game of social media use

Equilibrium in the Parent-Child game

Equilibrium	Type (θ)	Child's strategy (σ_1)		Parent's strategy (σ_2)	
		Bad mood	Good mood	Bad mood	Good mood
MPE	Not sensitive	Use	Use	Lenient	Lenient
	Sensitive	Don't	Use	Lenient	Lenient
MOE	Not sensitive	Use	Use	Strict	Lenient
	Sensitive	Use	Use	Strict	Lenient

Note: MPE refers to Markov perfect equilibrium. MOE refers to maximum-entropy observation-consistent equilibrium.

Relation to dynamic structural econometrics

Rational expectations (RE) assumption

- “Ubiquitous” even though it’s a “very strong assumption”
(Aguirregabiria and Mira, 2010)
- Relaxing it requires modeling or estimating beliefs
(e.g., Aguirregabiria and Jeon, 2020)

Maximum-entropy belief assumption

- Offers a viable alternative to RE with a point-prediction on beliefs
- Only requires an existing model + observational structure C

Takeaway

Use my solution concept if you want to . . .

- allow **causal misperception** in a dynamic model
- let misperception arise **endogenously** from the observational structure, and
- want **narrow predictions**

Takeaway

Use my solution concept if you want to . . .

- allow **causal misperception** in a dynamic model
- let misperception arise **endogenously** from the observational structure, and
- want **narrow predictions**

Thank you!
